Prevention of Stroke in Patients With Atrial Fibrillation

Combination of Aspirin and Clopidogrel

ACTIVE-A, a double-blind randomized trial, compared clopidogrel (75 mg/day) plus aspirin (75 to 100 mg/day) to aspirin alone in patients with AF at risk for stroke but who were unsuitable for therapy with vitamin K antagonists (VKAs). The combined antiplatelet therapy was demonstrated to be superior to aspirin alone, with a 28% reduction in stroke (RR, 0.72; 95% CI, 0.62 to 0.83; $P < .001$). Dual antiplatelet therapy, however, was associated with higher risk of major bleeding (RR, 1.57; 95% CI, 1.29 to 1.92; $P < .001$).⁸
